# The amazing CRISPR enzyme clan

**Cas9 | The OG**
Good at cutting DNA, great for knockouts. Already being replaced by newer base pair editors with more fine-tuned control.

**Cpf1 | The Stickler**
Like Cas9 but not as sloppy. It leaves "sticky" DNA ends, which are easier to work with when making edits.

**Cas13 | The Cowboy**
Cuts RNA not DNA. Could knock down protein levels without permanently changing your genome. Pair it with a reporter signal and you've got a diagnostic.

**Cas3 | The Gobbler**
Cas3 gives zero f***. It offers no repair mechanism—once it finds that target DNA sequence it just starts cutting till there ain't no DNA left.

**CasX/CasY | The X/Y Factor**
Just discovered in an abandoned silver mine, we don't know yet what these tiny enzymes' superpowers will be.

(Wired, march 2019)

# RNA-programmed endonucleases offer a variety of genome editing-options

PRO

- Target design simplicity;
- Higly efficiency
- Fast (4 weeks for mice);

CONS

- **fidelity**
- **delivery**
- **targeting scope**

- OPEN QUESTIONS:
- **Immunogenicity of nucleases *in vivo* (?)**
- **Ethics (?)**

# I - targeting scope

| Enzyme name | Size (residues) | PAM requirement and cleavage pattern |
|---|---|---|
| SpCas9 / FnCas9 | 1368 / 1629 |  |

# Baby gene edits could affect a range of traits

*Gene targeted for its role in HIV is linked to increased severity of other infectious diseases — and has implications for learning in mice.*

The CCR5 protein is expressed on the surface of some immune cells, and HIV takes advantage of it to sneak into the cells. In 1996, scientists identified a mutation, known as *CCR5-Δ32*, that makes carriers highly resistant to HIV

found naturally in about 10% of Europeans

Scientists analysing his presentation slides say that, instead, He seems to have produced three different mutations in the girls. It is expected that these mutations will have disabled the gene.

Slides from He's presentation suggest that both copies of the gene were disabled in one of the twins. The other twin seems to have at least one working copy

**NEWS** · 12 DECEMBER 2018 nature

# Baby gene edits could affect a range of traits

*Gene targeted for its role in HIV is linked to increased severity of other infectious diseases — and has implications for learning in mice.*

CCR5 also helps to protect the lungs, liver and brain during some other serious infections and chronic diseases.

Philip Murphy, an immunologist at the National Institute of Allergy and Infectious Diseases in Bethesda, Maryland, has done experiments that show that people without a functional CCR5 gene are four times more likely than those with the gene to develop these serious conditions. “CCR5 deficiency is not benign,” he says.

Influenza could also pose a greater risk to the twins . Work in mice has shown that the CCR5 protein helps to recruit key immune cells to fight the virus in the lungs

Scientists have also found that, among people with multiple sclerosis, those with the CCR5-Δ32 deletion are twice as likely to die early than are people without the mutation
